## Overview of study design

In this study we aimed to estimate the mean of systolic and diastolic blood pressure and the prevalence of raised blood pressure by sex and age across all provinces of Iran from 1990 to 2016. Raised blood pressure is defined as systolic blood pressure equal or greater than 140 mmHg and/or diastolic blood pressure equal or greater than 90 mmHg or being under treatment for hypertension. The population covered in this study included both sexes, 13 age groups from 25 to over 85 years (5-year categories), 31 provinces, and 27 years from 1990 to 2016.

We used various data sources for this study consisting of a pooled analysis and a comprehensive systematic review and meta-analysis. We also conducted a meta-regression model including Generalized Linear Mixed Model, Age-patio-Temporal, Gaussian Process Regression (ST-GPR), and crosswalk.

### Data sources:

- 1) Data retrieved through systematic review
- 2) National surveys
- 3) Subnational population-based studies

## Systematic Review

We conducted a comprehensive systematic review. In this review, only population-based studies were included in which, estimates were reported by sex and age, province, either mean SBP and/or DBP. We excluded studies that exclusively reported the prevalence of hypertension or pre-hypertension. In case the reported age range spanned over more than 5 years, the median estimate was used as the age category of that data point. The same strategy was used for year of the data point. Data points with a sample size less than 5 were also excluded. One added value of our study was splitting estimates of the age category of over 65 years into 5-year age categories till 85 years and more.

### Data Sources:

We searched three groups of data sources: 1) International databases; 2) Iranian databases; 3) Iranian data sources not indexed.

#### 1) *International Databases:*

- A) PubMed/MEDLINE
- B) Web of Science
- C) Scopus

## **2) Iranian Databases:**

- A) Scientific Information Database (SID)
- B) IranMedex (now known as Barekat)
- C) Irandoc
- D) Iranian journals not available online

## **Search Strategies:**

The adopted methods for systematic review include: defining the data sources and how to reach them, the search strategy for each data source, inclusion and exclusion criteria to select results of studies and reports, and methods for quality assessment, data extraction, and data synthesis.

We searched for related Mesh terms including all subheadings by using international and Iranian databases. The Persian keywords were equivalent to their English words and all probable combinations were considered.

### **1) International Databases:**

- A) PubMed/MEDLINE
- B) Web of Science
- C) Scopus

Search strategy was developed for MEDLINE, accessed via PubMed, based on an analysis of medical subject headings of key articles identified a priori. We used almost the same search terms for Web of Science and Scopus. We conducted a very sensitive search with broad terms in all three databases:

("blood pressure" OR hypertension OR prehypertension OR systolic OR diastolic OR "pulse pressure" OR hypertensive) AND (Iran OR Iranian OR Iranians OR Persia OR Persian OR Persians OR "I.R.Iran")

Filters Included:

- 1) Humans and adults
- 2) Publication date from 1990/1/1 to 2017/12/31
- 3) English and Persian Languages

### **2) Iranian Databases:**

- A) Scientific Information Database (SID)
- B) IranMedex
- C) Irandoc
- D) Iranian journals not available online

Both English and Farsi terms were used. English terms consist of entry terms used for international databases. As for the Farsi terms, the English terms were translated to Farsi and all plausible spellings were searched in Iranian search engines.

### **Selection Criteria:**

#### Inclusion criteria:

We included all cross-sectional studies and results of the first survey of population-based cohort studies that estimated mean systolic and / or diastolic blood pressure. All National, provincial, district and community studies from Jan 1990 to December 2017 that reported systolic blood pressure and/or diastolic blood pressure were included in the study. Studies were included if they have been from a representative sample, including from a national, subnational, or community population, and if the data has been based on measured (vs self-reported) blood pressure. If a published article met the inclusion criteria but did not report data by age and sex, we contacted the corresponding author to encourage him to contribute stratified data. Language of publication was restricted to English and Persian.

#### Exclusion criteria:

We excluded studies that their sampling method was non-random or their sample wasn't representative of Iran population. We also excluded studies that exclusively reported the prevalence of either hypertension or pre-hypertension

### **Implementation phases:**

#### *1. Study search and selection Process:*

Reviewers conducted title scans. If they were accepted, the article was promoted to the next level. The abstract review phase was designed to identify studies reporting the mean  $\pm$  SD and mean  $\pm$  SE of systolic and diastolic blood pressure. Abstracts were reviewed independently by two investigators, and were excluded if both investigators agreed that the article met one or more of the exclusion criteria (see inclusion and exclusion criteria listed above). Differences between investigators regarding abstract inclusion or exclusion were resolved through consensus.

Articles promoted on the basis of abstract review underwent another independent parallel review to determine if they should be included for data abstraction. Differences regarding article inclusion were resolved through consensus.

## II. *Quality assessment*

Article quality was assessed by Critical Appraisal Tool (CASP or EBL).

A) The following criteria were considered in quality assessment of blood pressure measurement:

- 1) Position of patient during blood pressure measurement;
- 2) Whether the arm has been measured to determine correct cuff size;
- 3) Training status of person taking blood pressure measurement;
- 4) Whether activities of participants with the preceding 30 minutes have been asked;
- 5) Number of times blood pressure has been measured;
- 6) Resting time between each measurement if more than one measurement made;
- 7) The time period during which patients had been resting before blood pressure measurement;
- 8) Type of instrument used for measurement;

B) The following criteria were considered in quality assessment of data source:

- 1) Response rate;
- 2) Sample size by gender;
- 3) Sampling design.

## III. *Data extraction*

Data extraction form was defined by main researchers. Study characteristics and study data were extracted into an excel worksheet.

### **National Surveys and Subnational Population-based studies:**

During the systematic review, we came across published reports of a number of National Surveys and large population-based cohort studies.

Two types of national surveys were available:

First: Seven iterations of NCD surveillance survey (STEPwise) in 2005, 2006, 2007, 2008, 2009, 2011, and 2016.

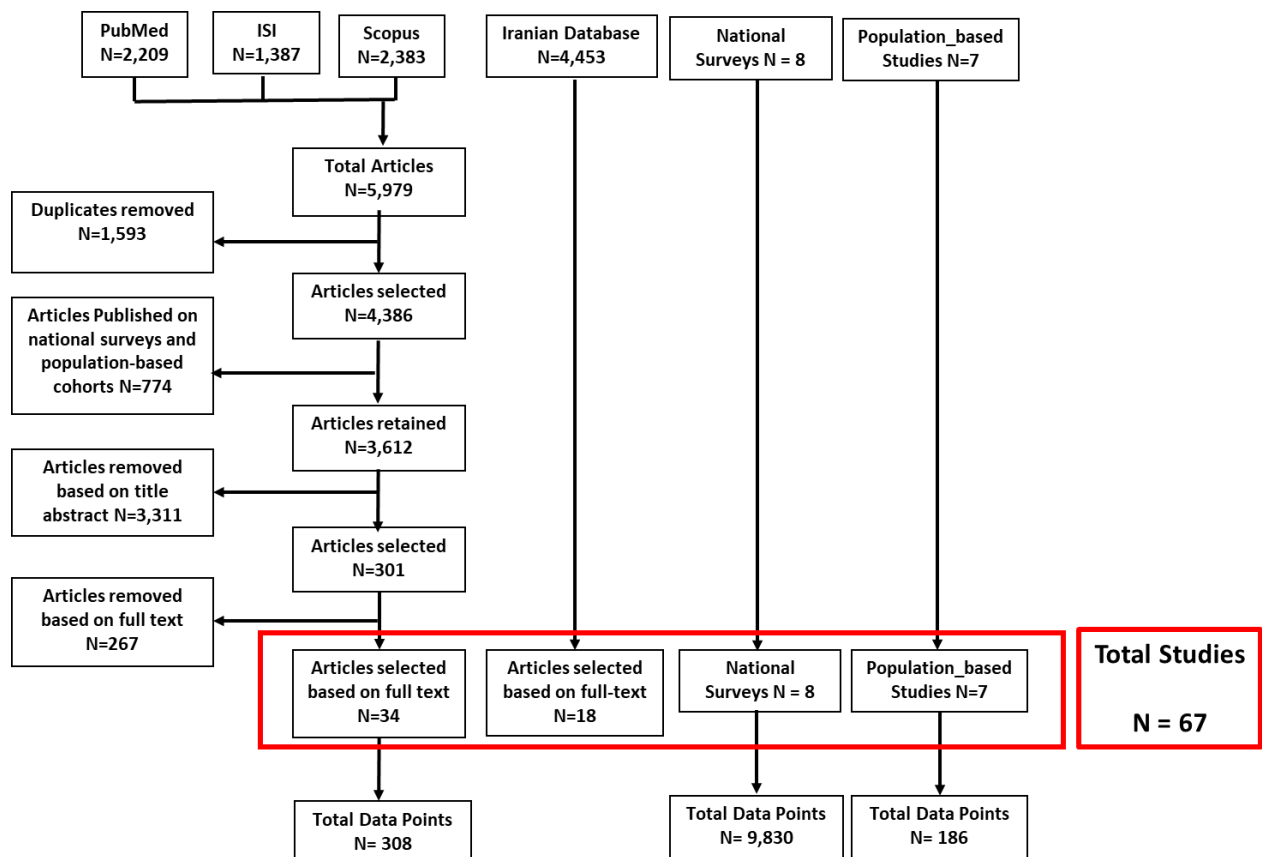

Second: One iteration of National Health Survey (NHS) in 2000

For these national sources, data on mean SBP and DBP were already reported by sex, 5-year age groups, province, and year. In these studies, blood pressure was measured three times. In our estimates we used only the mean of the second and third measurements. No other data cleaning or harmonization was required. Data at Individual level were added.

As for population-based cohort studies, we contacted the principal investigators of these studies to obtain a set of aggregated data which were pooled into our database. These included 7 provincial population based studies:

- 1) Golestan Cohort Study (GCS)
- 2) Pars Cohort Study (PCS)
- 3) Isfahan Healthy Heart Program (IHHP)
- 4) Tehran Lipid and Glucose Study (TLGS)
- 5) Kerman Cohort Study (KERCADRS)
- 6) Mashad Cardiovascular Cohort Study
- 7) Persian Gulf Healthy Heart Study

For subnational population-based studies, aggregated data were obtained. Estimates were again made by sex and 5-year age groups in defined provinces. In case the recruitment of the study took more than one year, the median over the year range was used.

## **Data Preparation**

In order to estimate the primary outcomes of this study, including: the mean of systolic and diastolic blood pressure, all combined data sources have to be prepared for statistical analysis. Each sex-age-province-year combination in systematic reviews that had not the information of year and province was excluded from analysis. In addition, plausible ranges in age groups and years computed as the median of this range. Studies with sample size less than 5 were also deleted.

In the last stage, according to the rare number of data points in age groups over 65 years, data points were adjusted for these age groups. To be more detailed, we used STEPs 2016 information for older age groups to estimate data points for NCDs studied in 2005, 2006, 2007, 2008, 2009, and 2011.

### **Covariates: years of schooling, wealth, urbanization**

In order to estimate the response variable including the mean of systolic and diastolic blood pressure and the prevalence of raised blood pressure, we used four types of covariates by all sex, age, province and year combinations.

Urbanization covariate is the proportion of the people who live in urban areas. This was calculated by population file in each province. Years of schooling (YOS) and wealth index (WI) were driven from Household Expenditure and Income which were conducted by Statistical Centre of Iran. YOS is defined as the years that each person educated and ranged from 0 to 25 years. WI is categorized as five equal percentiles from the income and assets of each household.

## Statistical Analyses

### Generalized Linear Mixed Model

We used a Generalized Linear Mixed Model (GLMM) to estimate the mean of SBP and DBP by two sexes, 13 age groups, 31 provinces, over 27 years. In this model we took advantage of including years of schooling, wealth index, and urbanization as fixed-effects and province as random effects of GLMM. The predictions and residuals of our data points were extracted from this model to be used later in Age-Spatio-Temporal Model. This model has been reiterated separately for women and men.

$$Y_{a,y,p} = \beta_0 + \beta_i X_{i_{ayp}} + \beta_j Z_j + \beta_2 \times year + \pi_p + \varepsilon_{a,y,p}$$

Where:

a= age group

y= year index

p= province index

$\beta_i$  = coefficient on covariate i

$X_{i_{ayp}}$  = covariate i for observation a, y, p

$\beta_j$  = coefficient on age group

$Z_j$  = age dummy variables

$\beta_2$  = coefficient for year

$\pi_p$  = random intercept on province

$\varepsilon_{a,y,p} \sim N(0, \sigma_\varepsilon \bullet I)$

### ST-GPR: for mean SBP and DBP estimates

We assumed that the residuals extracted from GLMM have some variations that can't be captured in this model. We used age-Spatio-Temporal model to justify variances and correlations among age groups, time, and provinces. Three weight matrices were developed to multiply by the vector of residuals. In these matrices, adjacent years, age groups and provinces have more weights. These matrices were as follows:

Age matrix:

$$\omega_{a_{i,j}} = \frac{1}{e^{\varpi \times |age\ group_i - age\ group_j|}}$$

i is prediction age group and j is observation's age group. If i and j be the same age group, the weight receives 1. We had a 13\*13 matrix for this component.  $\varpi$  was defined as 1, and it can be increases for greater smoothing over age.

Temporal matrix:

$$\omega_{y_{i,j}} = \left( 1 - \left( \frac{|year_i - year_j|}{\arg \max(|year_i - year_j| + 1)} \right)^\lambda \right)^3$$

It was a 27\*27 matrix with  $\lambda = 0.5$ . Again it can increase or decrease for the amount of smoothing across time.

The age and time weights are multiplied together for each observation, producing a weight for age and year dimensions.

$$\omega_{i,j} = \frac{\omega_{a_{i,j}} \times \omega_{y_{i,j}}}{\sum (\omega_{a_{i,j}} \times \omega_{y_{i,j}})}$$

Then the weights are rescaled to reflect geographical proximity to observation being predicted by a spatial 31\*31 matrix. The same provinces got the weight 1, adjacent provinces got the weight 0.9 and the other got 0.

In addition to these three type of weights, we defined a weight for each data source. National data sources were received 0.9 of the total weights and the other sub-national and systematic reviews got 0.1.

Once these weights have been calculated, weighting every observation in the dataset relative to the one being predicted, it a simple matter of calculating a weighted average of the residuals from the mixed effects regression. This "predicted residual" is then added back onto the mixed effects prediction, creating an estimate that more closely takes into account aspects of the data that cannot be captured by a simple covariate model.

These adjusted residuals were added to the preceding predictions of GLMM. Therefore, we had estimations for all sex, age, province, and year combinations.

For unifying all data sources and estimating their uncertainty intervals over time, we used Gaussian Process Regression (GPR) that is a Bayesian statistical model with a mean function and a covariance function. Age Spatio-Temporal was used as the prior for mean function and Matern function as a prior for covariance. The Matern function has three parameters. The first parameter quantifies the deviation of data points from mean function. The second parameter identifies the

degree of smoothness across time. The third one specified the correlation of estimates over time. Our posterior which is the mean of SBP and DBP has a normal distribution defined as a Gaussian Process for its mean and the sampling error of data points for its variance component ( $\sigma^2$ ). This model is formulated as follows and details about the parameters were previously described.

$$Y \sim Normal(m, \sigma^2)$$

$$m \sim GP(M, C)$$

Where m had the Gaussian Process with Age-Spatial-Temporal as its mean function and Matern for covariance function.

### **Crosswalk: For hypertension prevalence estimation**

Our estimations so far consisted of mean SBP and DBP distribution. In order to interpolate the prevalence of raised blood pressure, we needed a model to convert SBP and DBP to prevalence of hypertension. We used the data of the 7 rounds of STEP in which both SBP and DBP as well as the age-specific prevalence of hypertension were measured and reported. A linear mixed model on the logarithm of prevalence of hypertension was developed using 4 covariates: years of schooling, wealth index, urbanization, and body mass index (BMI) in addition to the mean of SBP and the mean of DBP. Again, all estimates were specific to sex, age, province, and year. For calculating uncertainty interval, we simulated the confidents excluded from previous model and the matrix of variance-covariance of coefficients. We also included the standard error of SBP and DBP GPR estimates.

$$\ln(hypertension\_prevalence_{a,y,p}) = \beta_0 + \beta_i X_{i_{ayp}} + \beta_1 \times SBP + \beta_2 \times DBP + \pi_p + \varepsilon_{a,y,p}$$

### **Age Standardization of results**

In order to remove the age effect, all estimates were age standardized using the population of Iran tabulated by sex, age at national level in 2016.

### **Sensitivity Analysis**

We conducted a sensitivity analysis in two stages. The first stage we randomly masked 10 percent of our data points and then, we repeated all the models for the rest of 90 percent of data. We used four metrics to evaluate the performance of our in-sample validity: Root Mean Square Error (RMSE), Root Median Square Error, Median Relative Error, and Mean Relative Error of prediction models.

In the next stage we calculated the proportion of data points in our masked data set that were located in the 95% Uncertainty Interval of our 90 percent withheld data. For DBP, 96.6 percent

of 10% withheld data hold in 90% prediction of model and its uncertainty. This measure for SBP was 96.75 percent.

outcome	method	Root mean SE	Root median SE	Mean RE	Median RE
DBP	GLMM	0.000570363	0.0018131	0.037787	0.0286263
	ASTM	0.000229987	0.0008650	0.035796	0.0276997

## Decomposition analysis

We calculated the percent change in number of adults with hypertension. We decomposed the contribution of increased prevalence, population growth, and change in age structure to the percent change in the number of hypertensive adults. To estimate the contribution of increase in prevalence, we calculated the percent change in number of hypertensives that would occur since 1990 if population remained the same and only prevalence rose to its level in 2016. Vice versa, to estimate the contribution of both population growth and change in age structure, we calculated the percent change assuming the prevalence remained constant and population changed from 1990 to 2016. In order to decompose the contribution of change only due to population growth, we assumed that the age structure remained constant and population growth happened with the same age structure. Finally, to estimate the contribution of change in age structure, we assumed that the population and prevalence remained constant and only the age structure in 1990 changed to the age structure in 2016.
